Classificatio Problems

Regression

Revisiting the Bayes Rule

- We have n observations, each with a p dimensional covariate X, and a binary outcome Y.
- Training data: $\mathcal{D}_n = \{x_i, y_i\}_{i=1}^n$:
 - $-x_i \in \mathbf{R}^p$,
 - y_i ∈ {0,1} (we could use other codings).
- The goal is to find a (hard) classifier

$$f: \mathbf{R}^p \longrightarrow \{0,1\}$$

Classification Problems

Classification

S.Lan

Classificatio Problems

Regression

Revisiting th

Revisiting th Bayes Rule

Discriminant Analysis • Similar to the regression models, the optimal classifier is defined as the one that minimizes the risk, with a loss function

$$R(f) = E[L(Y, f(X))]$$

 The most common choice of L for classification problems is the 0–1 loss defined as

$$L(a,b) = \begin{cases} 0 & \text{if} \quad a = b \\ 1 & \text{if} \quad \text{o.w.} \end{cases}$$

Underlying Model

Classification

S.Lan

Classificatio Problems

Regression
Revisiting th

Revisiting th Bayes Rule

Discriminant Analysis • We can assume that the underlying model for the probability of Y=1 at each target point x_0 is

$$\eta(x_0) = P(Y = 1 | X = x_0)$$

 What is the best classifier? If we use the 0–1 loss, we try to find f to minimize

$$R(f) = \eta(x_0)I(f(x_0) = 0) + (1 - \eta(x_0))I(f(x_0) = 1)$$

• Hence, its better to choose $f(x_0) = 0$ if $\eta(x_0) < 1/2$ and 1 o.w.

Underlying Model

Classification

S.Lan

Classificatio Problems

Logistic Regressio

Revisiting the Baves Rule

Discriminan Analysis • Apply this to all possible points, we have the optimal rule

$$f_B(x) = \operatorname*{arg\,min}_f \, \mathsf{R}(f) = egin{cases} 1 & \mathrm{if} & \eta(x) > 1/2 \\ 0 & \mathrm{if} & \eta(x) \leq 1/2. \end{cases}$$

- Note: if $\eta(x) = 1/2$, it doesn't matter what the decision rule is because the loss is 1/2 either way.
- This optimal rule is called the Bayes Rule, and the corresponding risk $R(f_B)$ is referred to as the Bayes risk or Bayes error.
- We introduce two approaches: logistic regression and discriminate analysis.

Motivation

Classification

S.Lan

Classificatio Problems

Logistic Regression

Revisiting the Bayes Rule

Discriminant Analysis

- The logistic regression belongs to a class of generalized linear models (GLM)
- In linear regression, we have $Y = X^{\mathsf{T}}\beta + \epsilon$, however, the outcome is continuous.
- When Y takes only 0 or 1, we can model it using a Bernoulli distribution, i.e.,

$$Y \sim \mathsf{Ber}(p)$$

• To incorporate covariates, we let $p = \eta(x)$, hence, the conditional distribution is

$$Y|X = x \sim \operatorname{Ber}(\eta(x))$$

Motivation

Classification

S.Lan

Classification Problems

Logistic Regressio

Revisiting the Bayes Rule

Discriminant Analysis

- We can choose many functional forms of $\eta(\cdot)$, however, linear functions seems to be the most convenient and interpretable.
- This motivate us to consider some link function ϕ that transform $\eta(x)$ into $x^{\mathsf{T}} \boldsymbol{\beta}$

$$\phi(\eta(x)) = x^{\mathsf{T}}\beta$$

 For logistic regression, we use the logit link function, which is also called the log-odds:

$$\phi(a) = \mathsf{logit}(a) = \mathsf{log}\left(\frac{a}{1-a}\right)$$

Classification Problems

Logistic Regression

Bayes Rule

Discriminant Analysis • From some simple derivations, if we set

$$\mathsf{logit}(\eta(x)) = x^{\mathsf{T}} \boldsymbol{\beta}$$

then

$$\log \frac{\eta(x)}{1 - \eta(x)} = x^{\mathsf{T}} \beta$$

$$\implies \eta(x) = \frac{\exp(x^{\mathsf{T}} \beta)}{1 + \exp(x^{\mathsf{T}} \beta)}$$

• Hence, for logistic regression, the conditional distribution of Y given X = x is

$$\mathsf{Ber}\left(\frac{\mathsf{exp}(x^\mathsf{T}\beta)}{1+\mathsf{exp}(x^\mathsf{T}\beta)}\right)$$

Fitting Logistic Models

Classification

S.Lan

Classification Problems

Logistic Regressio

Revisiting the Bayes Rule

Discriminant Analysis

- ullet The common technique for solving the eta parameters is through maximizing the log-likelihood
- ullet Since the response variable Y follows a Bernoulli distribution, the likelihood for a single observation is

$$p(Y = y_i | X = x_i) = \eta(x_i)^{y_i} [1 - \eta(x_i)]^{1 - y_i}$$

• Using the logit link function, and a set of observations $\{x_i, y_i\}_{i=1}^n$, we have

$$\ell(\boldsymbol{\beta}) = \sum_{i=1}^n \log p(y_i|x_i,\boldsymbol{\beta})$$

Fitting Logistic Models

Classification

S.Lan

Classificatio Problems

Logistic Regression

Bayes Rule

Discriminant Analysis • This can be simplified into

$$\ell(\beta) = \sum_{i=1}^{n} \log \left\{ \eta(x_i)^{y_i} [1 - \eta(x_i)]^{1 - y_i} \right\}$$

$$= \sum_{i=1}^{n} y_i \log \frac{\eta(x_i)}{1 - \eta(x_i)} + \log[1 - \eta(x_i)]$$

$$= \sum_{i=1}^{n} y_i x_i^{\mathsf{T}} \beta - \log[1 + \exp(x_i^{\mathsf{T}} \beta)]$$

• Hence we solve for β that maximizes the log-likelihood

$$\widehat{oldsymbol{eta}} = rg\max_{oldsymbol{eta}} \, \ell(oldsymbol{eta})$$

Newton-Raphson

Classification

S.Lan

Classification Problems

Logistic Regression

Revisiting the Bayes Rule

Discriminant Analysis

- To solve for $\widehat{\beta}$, we use Newton's method (second order method)
- Choose an initial value β^0 , then update β by

$$oldsymbol{eta}^{\, ext{new}} = oldsymbol{eta}^{\, ext{old}} - \left[rac{\partial^2 \ell(oldsymbol{eta})}{\partial oldsymbol{eta} \partial oldsymbol{eta}^{\, ext{T}}}
ight]^{-1} rac{\partial \ell(oldsymbol{eta})}{\partial oldsymbol{eta}}$$

where

$$\begin{array}{ll} \text{(gradient)} & \frac{\partial \ell(\boldsymbol{\beta})}{\partial \boldsymbol{\beta}} = \sum_{i=1}^n y_i x_i - \sum_{i=1}^n \frac{\exp(x_i^\mathsf{T} \boldsymbol{\beta}) x_i}{1 + \exp(x_i^\mathsf{T} \boldsymbol{\beta})} \\ \text{(Hessian)} & \frac{\partial^2 \ell(\boldsymbol{\beta})}{\partial \boldsymbol{\beta} \partial \boldsymbol{\beta}^\mathsf{T}} = - \sum_{i=1}^n x_i x_i^\mathsf{T} \eta(x_i) [1 - \eta(x_i)] \end{array}$$

Penalized Logistic Regression

Classification

S.Lan

Classificatio Problems

Logistic Regression

Revisiting th Bayes Rule

Discriminant Analysis

- When the number of variables is large, we may consider a sparse model. The idea is similar to Lasso or Ridge in linear regressions.
- Ridge penalty

$$\widehat{oldsymbol{eta}} = \mathop{\mathsf{arg\,min}}_{oldsymbol{eta}} \ -2\ell(oldsymbol{eta}) + \lambda \|oldsymbol{eta}\|^2$$

Lasso penalty

$$\widehat{oldsymbol{eta}} = \mathop{\mathsf{arg\,min}}_{oldsymbol{eta}} \ -2\ell(oldsymbol{eta}) + \lambda \|oldsymbol{eta}\|_1$$

Classification

S.Lan

Classificatio Problems

Regression

Revisiting the Bayes Rule

Discriminan Analysis

- Instead of modeling the conditional probability, we may consider to view the problem in a different way.
 - Recall that we simply need the decision rule to be

$$f_B(x) = \begin{cases} 1 & \text{if} \quad \eta(x) > 1/2 \\ 0 & \text{if} \quad \eta(x) \leq 1/2. \end{cases}$$

Essentially, we just need to compare

$$P(Y = 1 | X = x)$$
 vs. $P(Y = 0 | X = x)$

Classification

S.Lan

Classificatio Problems

Regression

Revisiting the Bayes Rule

Discriminant Analysis • We can apply the Bayes rule:

$$P(Y = 1|X = x) = \frac{P(X = x|Y = 1)P(Y = 1)}{P(X = x)}$$

$$P(Y = 0|X = x) = \frac{P(X = x|Y = 0)P(Y = 0)}{P(X = x)}$$

- Here we need a few additional quantities: the priors and the conditional probabilities.
- Noticing that the denominator does not play a role in the comparison.

Classification

S.Lan

Classification Problems

Logistic Regression

Revisiting the Bayes Rule

Discriminan

• Let prior probabilities be

$$\pi = P(Y = 1)$$
 and $(1 - \pi) = P(Y = 0)$

and define the conditional densities of X as

$$f_1 = P(X = x | Y = 1)$$
 and $f_0 = P(X = x | Y = 0)$.

The Bayes rule can also be written as

$$f_B(x) = \begin{cases} 1 & \text{if } \pi f_1(x) > (1-\pi)f_0(x) \\ 0 & \text{o.w.} \end{cases}$$

Classification

S.Lan

Classificatio Problems

Regression

Revisiting the Bayes Rule

- The prior probabilities: P(Y = 0) and P(Y = 1)
 - Prior knowledge of the likelihood of occurrence for each class
 - May be used to make a decision without any extra knowledge
- The posterior probabilities: P(Y|X)
 - The updated probabilities after observing X = x
- Bayes decision rule combines them to achieve the minimum risk

$$f_B(x) = 1$$
 if $\frac{f_1(x)}{f_0(x)} > \frac{1-\pi}{\pi}$; and 0 o.w.

Classification

S.Lan

Classification Problems

Logistic Regression

Revisiting the Bayes Rule

Discriminant Analysis • The decision boundary can be used to describe the optimal rule:

$${x : \pi f_1(x) = (1 - \pi) f_0(x)}$$

• Linear methods for classification: the classification rules with $f_B(x)$ being linear in x, or equivalently, classification rules with linear decision boundaries.

Multi-Class Problems

Classification

S.Lan

Classification Problems

Regression

Revisiting the Bayes Rule

Discriminant Analysis • The Bayes rule can be easily generated to multi-class problems, where $y \in \{1, ..., K\}$. The classifier is

$$f: \mathbf{R}^p \longrightarrow \{1, \dots, K\}$$

• The optimal rule is

$$f_B(x) = \underset{k}{\operatorname{arg \, max}} \ P(Y = k | X = x) = \underset{k}{\operatorname{arg \, max}} \ \pi_k f_k(x)$$

where π_k is prior probability and $f_k(x)$ is the conditional density.

• Classify x to the most probable class by comparing P(Y|X=x), or the product of prior and conditional density.

Binary vs. Multi-Class

Classification

S.Lan

Classificatio Problems

Regression

Revisiting the Bayes Rule

Discriminant Analysis

- Many binary classifiers can also handle multi-classes, such as discriminate analysis (LDA, QDA, NB), logistic regression, kNN and random forests. But for some others, the extension is non-trivial (e.g. SVM).
- There are some naive (although may not be optimal) ways to apply a binary classifier on a classification problem with K > 2 categories.
 - Train K one-vs-other classifiers
 - Train K(K-1)/2 pairwise classifiers

Then we can combine the results to get a consensus prediction.

Table of Contents

Classification

Classificatio Problems

Logistic Regression

Revisiting the Bayes Rule

- Classification Problems
 - 2 Logistic Regression
- 3 Revisiting the Bayes Rule
- 4 Discriminant Analysis

A Motivation

Classification

S.Lan

Classification Problems

Regression

Revisiting the Bayes Rule

- Lets look at a naive approach: "1 vs. others". The following example is demonstrated by fitting a linear regression for categorical outcomes, mainly for easy understandings (although logistic regression is a better choice).
- For the outcome Y, which may fall into categories $1, \ldots, K$, define a vector of indicators (Y_1, \ldots, Y_K)

$$Y_k = 1$$
 if $Y = k$

- Each vector (Y_1, \ldots, Y_K) has a single 1.
- The n training samples form an $n \times K$ indicator response matrix \mathbf{Y} , where each row is such an indicator vector.

The Masking Problem

Classification

S.Lan

Classificatio Problems

Regression

Bayes Rule

Discriminant Analysis • Fit a linear regression model to each column of Y simultaneously

$$\widehat{\boldsymbol{Y}} = \boldsymbol{X} (\boldsymbol{X}^{\mathsf{T}} \boldsymbol{X})^{-1} \boldsymbol{X}^{\mathsf{T}} \boldsymbol{Y} \equiv \boldsymbol{X} \widehat{\boldsymbol{B}}$$

- The k'th column of the parameter matrix B represents the coefficients for modeling the "likelihood" of being in category k
- Suppose we have a new input x, we can compute $\widehat{f}_k(x) = x^T \mathbf{B}_{[,k]}$, and compare them to predict the class using

$$Y_{\text{pred}} = \widehat{f}(x) = \underset{k=1,...K}{\operatorname{arg max}} \ \widehat{f_k}(x)$$

- However, this suffered from some problems:
 - No guarantee that each $\widehat{f}_k(x) \in [0,1]$
 - Serious masking problem for $K \geq 3$

Masking Problems

Classification

S.Lan

Classificatio Problems

Logistic Regression

Revisiting the

Discriminant Analysis

Fitting the three-class problem using polynomials

$$\mathsf{Degree} = 1; \, \mathsf{Error} = 0.33$$

$$Degree = 2, Error = 0.04$$

Note: LDA can avoid this problem as it is shown in the previous plot.

Linear Discriminant Analysis

Classification

S.Lan

Classificatio Problems

Regression

Revisiting the Bayes Rule

- The idea is to model the distribution of X in each of the classes separately, and then use Bayes theorem to flip things around and obtain P(Y|X=x).
- Linear Discriminant Analysis (LDA)
- Quadratic Discriminant Analysis (QDA)
- Naive Bayes (NB)

Bayes Theorem for Classification

Classification

S.Lan

Classificatio Problems

Regression

Revisiting the Bayes Rule

Discriminant Analysis As we demonstrated earlier (Bayes rules), the conditional probability can be formulated using Bayes Theorem:

$$P(Y = k | X = x) = \frac{P(X = x | Y = k)P(Y = k)}{P(X = x)}$$

$$= \frac{P(X = x | Y = k)P(Y = k)}{\sum_{l=1}^{K} P(X = x | Y = l)P(Y = l)}$$

$$= \frac{\pi_k f_k(x)}{\sum_{l=1}^{K} \pi_l f_l(x)}$$

where $f_k(x)$ is the conditional density function of X|Y=k, and $\pi_k = P(Y=k)$ is the prior probability.

Discriminant Analysis • The best prediction is picking the one that maximizing the posterior

$$\underset{k}{\operatorname{arg\,max}} \ \pi_k f_k(x)$$

- Linear discriminate analysis (LDA) assumes that $f_k(x)$ is normal density
- Suppose we model each class density as multivariate Gaussian $\mathcal{N}(\mu_k, \Sigma_k)$, and assume that the covariance matrices are the same across all k, i.e., $\Sigma_k = \Sigma$. Then the

$$f_k(x) = \frac{1}{(2\pi)^{p/2} |\Sigma|^{1/2}} \exp\left[-\frac{1}{2}(x - \mu_k)^\mathsf{T} \Sigma^{-1}(x - \mu_k)\right]$$

Classification

S.Lan

Classification Problems

Regression

Revisiting the Bayes Rule

Discriminant Analysis • The log-likelihood function for the conditional distribution is

$$\log f_k(x) = -\log((2\pi)^{p/2}|\Sigma|^{1/2}) - \frac{1}{2}(x - \mu_k)^{\mathsf{T}}\Sigma^{-1}(x - \mu_k)$$
$$= -\frac{1}{2}(x - \mu_k)^{\mathsf{T}}\Sigma^{-1}(x - \mu_k) + \text{constant}$$

 Hence we just need to select the category that attains the highest posterior density (MAP: maximum a posteriori):

$$\begin{split} Y_{pred} &= \widehat{f}(x) = \underset{k}{\text{arg max}} \ \log \left(\pi_k f_k(x) \right) \\ &= \underset{k}{\text{arg max}} \ -\frac{1}{2} (x - \mu_k)^\mathsf{T} \Sigma^{-1} (x - \mu_k) + \log(\pi_k) \end{split}$$

Interpretations of LDA

Classification

S.Lan

Classification Problems

Regression

Revisiting the Bayes Rule

- The term $(x \mu_k)^T \Sigma^{-1} (x \mu_k)$ is simply the Mahalanobis distance between x and the centroid μ_k for class k
- Classify x to the class with the closest (in terms of Mahalanobis distance) centroid, while also adjust for the prior.
- Special case: $\Sigma = I$ (only Euclidean distance is needed)

$$\arg\max_{k} -\frac{1}{2} ||x - \mu_{k}||^{2} + \log(\pi_{k})$$

Decision Boundary

Classification

S.Lan

Classification Problems

Logistic Regressic

Revisiting the Bayes Rule

Discriminant Analysis • Noticing that that quadratic term can be simplified to

$$\begin{split} &-\frac{1}{2}(x-\mu_k)^\mathsf{T} \Sigma^{-1}(x-\mu_k)\\ &= x^\mathsf{T} \Sigma^{-1} \mu_k - \frac{1}{2} \mu_k^\mathsf{T} \Sigma^{-1} \mu_k + \text{irrelevant constants} \end{split}$$

• Then the discriminant function is defined as

$$\delta_k(x) = x^\mathsf{T} \Sigma^{-1} \boldsymbol{\mu}_k - \frac{1}{2} \boldsymbol{\mu}_k^\mathsf{T} \Sigma^{-1} \boldsymbol{\mu}_k + \log \pi_k$$
$$= \mathbf{w}_k^\mathsf{T} x + b_k,$$

• We can calculate \mathbf{w}_k 's and b_k 's for each class k from the data.

Decision Boundary

Classification

S.Lan

Classificatio Problems

Regression

Revisiting the Bayes Rule

Discriminant Analysis • The decision boundary function between class k and l is

$$\mathbf{w}_{k}^{\mathsf{T}}x + b_{k} = \mathbf{w}_{l}^{\mathsf{T}}x + b_{l}$$

$$\Leftrightarrow (\mathbf{w}_{k} - \mathbf{w}_{l})^{\mathsf{T}}x + (b_{k} - b_{l}) = 0$$

$$\Leftrightarrow \widetilde{\mathbf{w}}^{\mathsf{T}}x + \widetilde{b} = 0$$

• Since $\mathbf{w}_k = \Sigma^{-1} \mu_k$ and $\mathbf{w}_l = \Sigma^{-1} \mu_l$, the decision boundary has the directional vector

$$\widetilde{\mathbf{w}} = \mathbf{\Sigma}^{-1}(\boldsymbol{\mu}_k - \boldsymbol{\mu}_l)$$

Interpretations of LDA

Classification

S.Lan

Classification

Logistic Regression

Revisiting th Baves Rule

FIGURE 4.9. Although the line joining the centroids defines the direction of greatest centroid spread, the projected data overlap because of the covariance (left panel). The discriminant direction minimizes this overlap for Gaussian data (right panel).

Parameter Estimations in LDA

Classification

S.Lan

Classification Problems

Regression

Revisiting the Bayes Rule

- We estimate the LDA parameters from the training data
 - Prior probabilities: $\widehat{\pi}_k = n_k/n = n^{-1} \sum_k \mathbf{1}\{y_i = k\}$, where n_k is the number of observations in class k.
 - Centroid: $\widehat{\mu}_k = n_k^{-1} \sum_{i: y_i = k} x_i$
 - Pooled covariance (since we assume that covariance matrices are the same across different classes):

$$\widehat{\Sigma} = \frac{1}{n - K} \sum_{k=1}^{K} \sum_{i: y_i = k} (x_i - \widehat{\mu}_k) (x_i - \widehat{\mu}_k)^{\mathsf{T}}$$

Quadratic Discriminant Analysis

Classification

S.Lan

Classification Problems

Regression

Revisiting the

Bayes Rule

Discriminant Analysis

- Quadratic Discriminant Analysis (QDA) simply abandons the the common covariance matrix assumption. Hence, the Σ_k 's are not equal.
- In this case, the determinant $|\Sigma_k|$ of each covariance matrix will be different. The MAP decision becomes

$$\begin{aligned} & \max_{k} \log \left(\pi_{k} f_{k}(x) \right) \\ &= \max_{k} - \frac{1}{2} \log |\Sigma_{k}| - \frac{1}{2} (x - \mu_{k})^{\mathsf{T}} \Sigma_{k}^{-1} (x - \mu_{k}) + \log(\pi_{k}) \\ &= x^{\mathsf{T}} \mathbf{W}_{k} x + \mathbf{w}_{k}^{\mathsf{T}} x + b_{k} \end{aligned}$$

• A quadratic decision boundary between class k and l

$$\{x: x^{\mathsf{T}}(\mathbf{W}_k - \mathbf{W}_l)x + (\mathbf{w}_k^{\mathsf{T}} - \mathbf{w}_l^{\mathsf{T}})^{\mathsf{T}}x + (b_k - b_l) = 0\}$$

Estimations in QDA

Classification

S.Lan

Classificatio Problems

Regression

Revisiting the Bayes Rule

- We estimate the QDA parameters from the training data
 - Prior probabilities: $\widehat{\pi}_k = n_k/n = n^{-1} \sum_k \mathbf{1}\{y_i = k\}$, where n_k is the number of observations in class k.
 - Centroid: $\widehat{\mu}_k = n_k^{-1} \sum_{i: y_i = k} x_i$
 - Sample covariance matrix for each class:

$$\widehat{\Sigma}_k = \frac{1}{n_k - 1} \sum_{i: y_i = k} (x_i - \widehat{\mu}_k) (x_i - \widehat{\mu}_k)^{\mathsf{T}}$$

LDA vs. QDA

Classification

S.Lan

Classification Problems

Regression

Bayes Rule

- More parameters in QDA than LDA, especially when p is large
- Both are extremely simple to implement and perform well on real classification problems
- We can include selected quadratic terms of the covariates, such as X_1X_2 or X_1^2 , and still perform LDA

LDA vs. QDA

lassification

S.Lan

Classification

Logistic Regression

Revisiting th Bayes Rule

FIGURE 4.6. Two methods for fitting quadratic boundaries. The left plot shows the quadratic decision boundaries for the data in Figure 4.1 (obtained using LDA in the five-dimensional space $X_1, X_2, X_1X_2, X_1^2, X_2^2$). The right plot shows the quadratic decision boundaries found by QDA. The differences are small, as is usually the case.

Reduced Rank LDA

Classification

S.Lan

Classificatio Problems

Regression

Bayes Rule

- Low-dimensional structure of the data
 - The K centroids $(\mu_1, \dots \mu_K)$ in p-dimensional input space span a subspace of rank K-1, denote this subspace as H
 - For any point x, we can project it onto H, and make a comparison in this reduced space
 - Think of these K centroids (their differences) as basis of the space.
 - When $K \ll p$, this is a considerable drop in dimension
 - When K = 3, we can view the data in a two dimensional plot
 - When *K* is large, a natural way is to perform PCA on these *K* mean vectors (treating each centroid as an observation). They are usually called discriminant coordinates or canonical variates.

Discriminant Coordinates

Discriminant Analysis in Large p Problems

Classification

S.Lan

Classificatio Problems

Regression

Revisiting the Bayes Rule

- When p is large, QDA/LDA may not be applicable, because the inverse of $\widehat{\Sigma}$ may not exist
- Using generalized inverse matrix can easily overfit the data
- A warning sign: Classes are well-separated on the training data could be meaningless for high-dimensional data
- Regularization: sparse LDA, Naive Bayes, RDA

Regularized Discriminant Analysis (RDA)

Classification

S.Lan

Classificatio Problems

Revisiting the

Discriminant

• Friedman (1989): shrink the separate covariances of QDA toward a common covariance in LDA. Regularized covariance matrices are

$$\widehat{\Sigma}_k(\alpha) = \alpha \widehat{\Sigma}_k + (1 - \alpha)\widehat{\Sigma}$$

- $\alpha \in [0,1]$, a continuum of models between LDA and QDA, if $\widehat{\Sigma}$ is the pooled covariance matrix used in LDA
- In practice, chose α using CV.
- We can further shrink Σ_k towards the diagonal covariance, with $\gamma \in [0,1]$

$$\widehat{\Sigma}_k(\alpha, \gamma) = \alpha \widehat{\Sigma}_k + (1 - \alpha)\gamma \widehat{\Sigma} + (1 - \alpha)(1 - \gamma)\widehat{\sigma}^2 \mathbf{I}$$

Naive Bayes

Classification

S.Lan

Classification Problems

Logistic Regression

Revisiting the Bayes Rule

Discriminant Analysis • Recall that the optimal decision rule is

$$\underset{k}{\operatorname{arg\,max}} P(Y = k | X = x) = \underset{k}{\operatorname{arg\,max}} \pi_k f_k(x)$$

• We can approximate $f_k(x)$ by

$$f_k(x) \approx \prod_{j=1}^p f_{kj}(x_j),$$

meaning that each dimension of x is approximately independently

- $f_{kj}(x_j)$ can be estimated using histograms (discrete), or kernel densities (continuous)
- When Gaussian kernel is used, what is the connection to LDA?

Classificatio Problems

Regression

Bayes Rule

Discriminant Analysis • Make decision (classification) based on covariates (weather conditions).

So, probability of playing golf is given by:

$$P(Yes|today) = \frac{P(SunnyOutlook|Yes)P(HotTemperature|Yes)P(NormalHumidity|Yes)P(NoWind|Yes)P(Yes)P(Yes)P(Today)}{P(today)} = \frac{P(SunnyOutlook|Yes)P(HotTemperature|Yes)P(NormalHumidity|Yes)P(NoWind|Yes)P(Yes)P(Today)}{P(today)} = \frac{P(SunnyOutlook|Yes)P(HotTemperature|Yes)P(NormalHumidity|Yes)P(NoWind|Yes)P(Yes)P(Today)}{P(today)} = \frac{P(SunnyOutlook|Yes)P(HotTemperature|Yes)P(NormalHumidity|Yes)P(NoWind|Yes)P(Yes)P(Today)}{P(today)} = \frac{P(SunnyOutlook|Yes)P(HotTemperature|Yes)P(NormalHumidity|Yes)P(NoWind|Yes)P(Yes)P(Today)}{P(today)} = \frac{P(SunnyOutlook|Yes)P(HotTemperature|Yes)P(NormalHumidity|Yes)P(NoWind|Yes)P(Yes)P(Today)}{P(today)} = \frac{P(SunnyOutlook|Yes)P(NoWind|Yes)P(Yes)P(Today)}{P(today)} = \frac{P(SunnyOutlook|Yes)P(Today)}{P(Today)} = \frac{P($$

and probability to not play golf is given by:

$$P(No|today) = \frac{P(SunnyOutlook|No)P(HotTemperature|No)P(NormalHumidity|No)P(NoWind|No)P(No)P(NoWind|No)P(No)P(NoWind|No)P(No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(NoWind|No)P(Nowind|No)P(NoWind|No)P(NoWind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No)P(Nowind|No$$

Since, P(today) is common in both probabilities, we can ignore P(today) and find proportional probabilities as:

$$P(Yes|today) \propto \frac{2}{9} \cdot \frac{2}{9} \cdot \frac{6}{9} \cdot \frac{6}{9} \cdot \frac{9}{14} \approx 0.0141$$

and

$$P(No|today) \propto \frac{3}{5} \cdot \frac{2}{5} \cdot \frac{1}{5} \cdot \frac{2}{5} \cdot \frac{5}{14} \approx 0.0068$$

Logistic Regression vs. LDA

Classification Problems

Regression

Revisiting the Bayes Rule

Discriminan Analysis • For LDA, the log-posterior odds between class 1 and 0 are linear in x

$$\log \frac{P(Y = 1|X = x)}{P(Y = 0|X = x)} = \log \frac{\pi_1}{\pi_0} - \frac{1}{2}\mu_1^{\mathsf{T}} \Sigma^{-1} \mu_1 + \frac{1}{2}\mu_0^{\mathsf{T}} \Sigma^{-1} \mu_0 + x^{\mathsf{T}} \Sigma^{-1} (\mu_1 - \mu_0)$$
$$= \alpha_0 + x^{\mathsf{T}} \alpha$$

Logistic model has linear logics by construction

$$\log \frac{P(Y = 1 | X = x)}{P(Y = 0 | X = x)} = \beta_0 + x^{\mathsf{T}} \beta$$

• Are they the same estimators?

Logistic Regression vs. LDA

Classification Problems

Regression

Revisiting the Bayes Rule

- For LDA, the The linearity is a consequence of the Gaussian assumption for the class densities, and the assumption of a common covariance matrix.
- For logistic regression, the linearity comes by construction.
- The difference lies in how the coefficients are estimated.
- Which is more general?
 - LDA assumes Gaussian distribution of X; while logistic leaves the density of X arbitrary
- Logistic model is more general
